Summary

What is already known about this topic?

Short-term exposure to air pollutants has been associated with chronic obstructive pulmonary disease (COPD) and asthma, which needs continuous observation.

What is added by this report?

This study uses the longest time series data so far from 2013 to 2018 and adds additional data analysis for ozone (O₃) to existing studies.

What are the implications for public health practice?

This study suggests that air pollutants have certain acute effects on outpatient and hospital admission of patients with COPD and asthma, which can be combined with the disease diagnosis and treatment guidelines to guide clinical practice.

Chronic obstructive pulmonary disease (COPD) and asthma are two major chronic airway diseases. Recent studies have focused on the relationship between air pollution and the development of acute exacerbations of COPD and asthma. In 2021, Liu et al. found that fine particulate matter (particles with aerodynamic diameter ≤ 2.5 μm ; PM_{2.5}) and nitrogen dioxide (NO₂) increased the risk of COPD and asthma (1). Doiron et al. found that PM_{2.5}, particles with aerodynamic diameter ≤ 10 μm (PM₁₀) and NO₂ significantly enhanced the morbidity of COPD (2). However, in 2014, a study found that neither NO₂ nor PM levels were associated with COPD morbidity (3). It can be concluded that there is no clear conclusion whether short-term exposure to air pollution increases the health risk of COPD and asthma patients. Meanwhile, in China, the available studies about air pollution are based on a three-year time series of data from 2013–2015 (4), which may not reflect the health effects of recent air quality improvement initiatives. Therefore, we analyzed daily outpatient and hospitalization data from the China CDC Disease Surveillance Point System (DSPs) from

January 1, 2013 to December 31, 2018 to explore the impact of short-term exposure to air pollution on the acute effects of patients with COPD and asthma.

This study collected inpatient and outpatient data for respiratory diseases, concentration of each air pollutant, as well as temperature and relative humidity data from January 1, 2013 to December 31, 2018 in 16 hospitals in China in 5 cities (6 districts and counties). We used the International Classification of Diseases Revision 10 (ICD-10) codes J40–J44 for COPD visits and codes J45–J46 for asthma. Relevant air pollution data was obtained from the National Urban Air Quality Real-Time Release Platform, and temperature and relative humidity was obtained from the National Meteorological Information Center.

Pollutant concentrations were aggregated to daily means [carbon monoxide (CO), sulfur dioxides (SO₂), NO₂, PM_{2.5}, and PM₁₀] and daily maximum 8-hour means (O₃).

We used a time-stratified case-crossover design to analyze the associations between air pollution and hospital admissions for respiratory diseases. A time stratum was defined as a combination of year, month, and day-of-week levels. This design allows for the adjustment of long-term and seasonal trends. We then fit a generalized linear model (GLM) with a Poisson distribution. Daily mean temperature and relative humidity were also controlled by the natural spline function in the model. The “stats” package in R software (version 4.0.2, R Foundation for Statistical Computing, Vienna, Austria) was used for analysis. Results were presented as the percentage changes and 95% confidence intervals (CIs) in daily inpatient and outpatient rates associated with a per 10 $\mu\text{g}/\text{m}^3$ increase in air pollutants (CO is mg/m^3). We also assessed the single-day lag effect (from 0 to 3) and the cumulative lag effect (0–1, 0–2, and 0–3) of air pollutants on daily outpatient and hospitalization rates.

In total, 85,961 outpatient visits and 62,381 hospital admissions were observed for COPD and asthma in 16 hospitals from 2013 to 2018.

Table 1 shows the mean pollutant concentrations,

TABLE 1. Daily counts of hospitalizations and outpatient visit for respiratory diseases and air pollution levels in China, 2013–2018.

| Variables | Mean (SD) |
|--|--------------|
| Outpatient visit (daily counts per county) | |
| COPD | 38 (18) |
| Asthma | 8 (5) |
| Hospitalizations (daily counts per county) | |
| COPD | 6 (4) |
| Asthma | 3 (2) |
| Pollutants | |
| PM _{2.5} (µg/m ³) | 59.1 (43.4) |
| PM ₁₀ (µg/m ³) | 95.9 (61.9) |
| O ₃ (µg/m ³) | 112.8 (59.3) |
| SO ₂ (µg/m ³) | 198.2 (17.2) |
| NO ₂ (µg/m ³) | 47.9 (21.3) |
| CO (mg/m ³) | 1.1 (0.7) |

Abbreviations: SD=standard deviation; COPD=chronic obstructive pulmonary disease; PM_{2.5}=particulate matter ≤2.5 m in diameter; PM₁₀=particulate matter ≤10 m in diameter; SO₂=sulfur dioxides; NO₂=nitrogen dioxide; CO=carbon monoxide; O₃=ozone.

and the average daily respiratory disease hospitalizations and outpatient visits in the study areas (expressed as mean and standard deviation). The average daily respiratory disease outpatient visits were approximately 38 for COPD and 8 for asthma, 6 for COPD, and 3 for asthma in daily hospital admissions.

Atmospheric pollutants had an acute effect on the risk of hospitalization for COPD (Figure 1A), and the acute effects of PM_{2.5}, O₃, and CO on the risk of hospitalization for COPD were most pronounced at lag02, with each 10 µg/m³ increase in PM_{2.5}, O₃, and CO increasing the risk of hospitalization for COPD by 1.1% (95% CI: 0.6%–1.7%), 1.7% (95% CI: 1.3%–2.1%), and 88.2% (95% CI: 6.7%–232%). However, no acute effect of air pollutants on the risk of hospitalization for asthma was seen (Figure 1B).

In patients with COPD, O₃ was negatively associated with an increased risk of outpatient visits for COPD (Figure 2A), and NO₂ was positively associated with increased risk of outpatient visits for COPD, most strongly at lag02, with each 10 µg/m³ increase in NO₂ associated with a 2.4% (95% CI: 0.4%, 4.4%) increase in risk of outpatient visits for patients with COPD.

Among asthma patients, PM_{2.5} and PM₁₀ were negatively associated with the risk of outpatient visits (Figure 2B), with the strongest at lag1, where each 10 µg/m³ increase in PM_{2.5} and PM₁₀ was associated

with a 0.6% (95% CI: –0.9%, –0.2%) and 0.4% (95% CI: –0.7%, –0.2%) decrease in the risk of outpatient visits for asthma patients, respectively. O₃, SO₂, and NO₂ were positively associated with increased risk of outpatient asthma visits and were strongest at lag02, with each 10 µg/m³ increase in O₃ and NO₂ increasing the risk of outpatient asthma visits by 0.9% (95% CI: 0.5%, 1.3%) and 2.9% (95% CI: 2%, 3.8%), respectively. The acute effect of SO₂ on outpatient asthma visits was strongest at lag2, with each 10 µg/m³ increase in SO₂ increasing the risk of outpatient visits for asthma patients by 1.1% (95% CI: 0.1%, 2.1%).

DISCUSSION

This study showed that air pollutants were related to increasing outpatient and hospitalization rates of chronic respiratory diseases. PM_{2.5}, O₃, and CO had an acute effect on the risk of hospitalization, and NO₂ was positively associated with an increased risk of outpatient visits for COPD. In asthma patients, O₃, SO₂, and NO₂ were positively associated with an increased risk of outpatient asthma visits. These results were basically consistent with the results of previous studies. Each 10 µg/m³ increase in PM_{2.5} was associated with a 1.61% increase in the risk of hospitalization for patients with COPD in the United States and 0.82% in Beijing (5–6).

The present study showed that CO was positively associated with the risk of hospitalization in patients with COPD, which was inconsistent with the results of previous relevant studies. A few epidemiological studies have found that low levels of CO may have a protective effect in some cases. A time-series study in Hong Kong, China showed that short-term exposure to CO was associated with a reduced risk of hospitalization for COPD (7). However, in Spain, a retrospective study found that elevated CO levels were associated with increased hospital admissions in patients with COPD (8), which was the same as our results. Therefore, further studies are needed to confirm the direct health effects of CO exposure on patients with COPD. At the same time, our study shows that PM_{2.5} and PM₁₀ were negatively associated with the risk of asthma outpatient visits, which was inconsistent with previous research results. A possible reason is that the concentrations of ozone and PM_{2.5} are seasonal and that asthma is affected by many factors. The overall confounders that could affect the association between pollutants and asthma exacerbations also need to be taken into

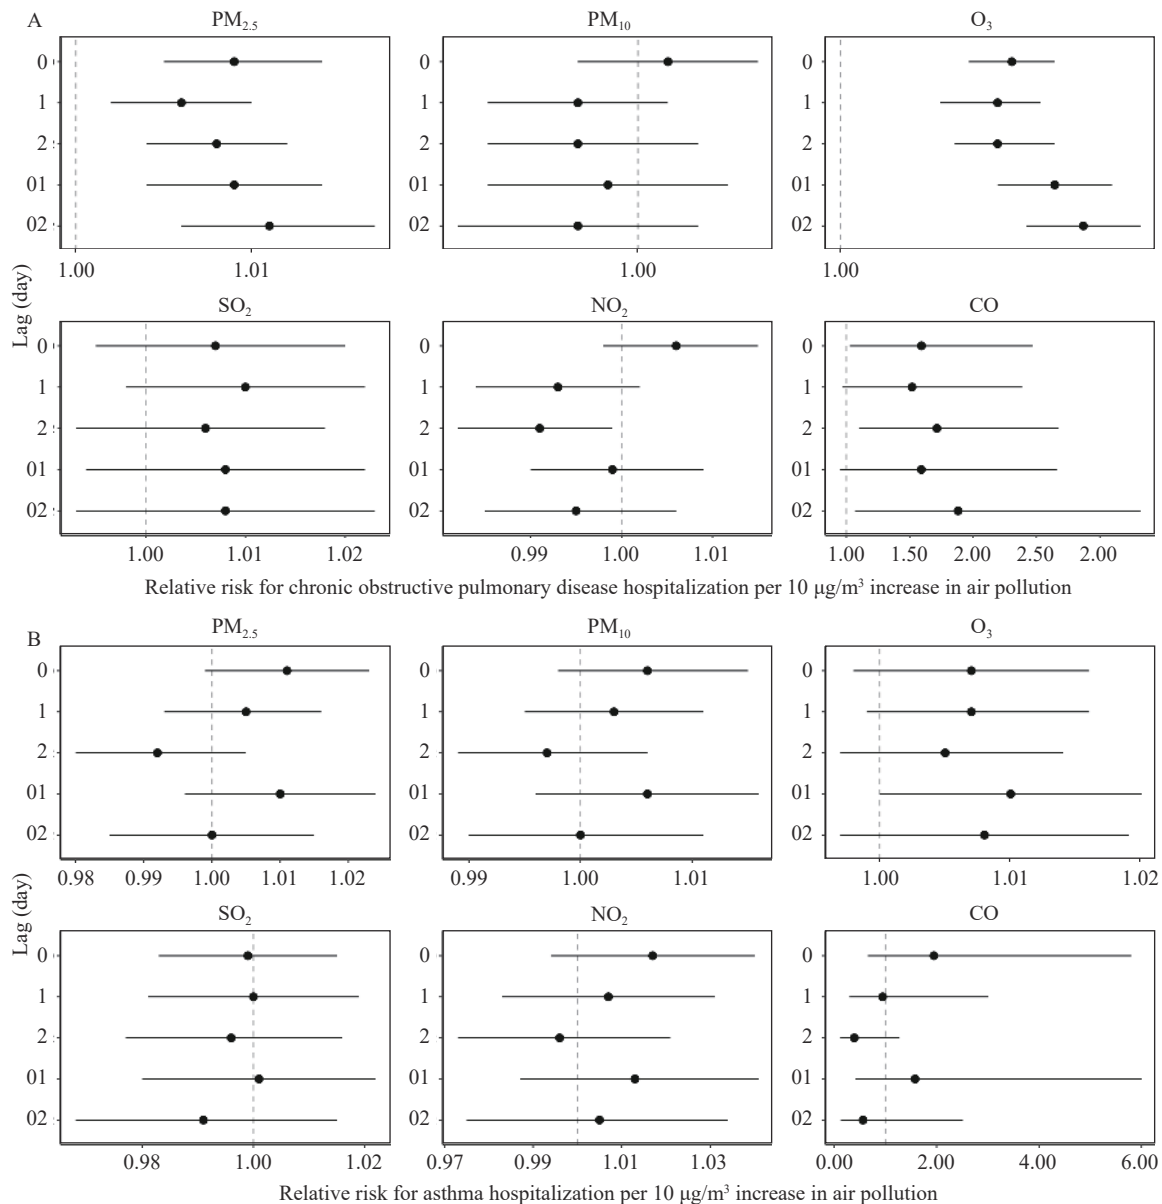

FIGURE 1. Relative risk for chronic obstructive pulmonary disease (A) and asthma (B) daily hospitalization per 10 $\mu\text{g}/\text{m}^3$ increase in concentrations of air pollutants with different lag days in 16 hospitals, 2013–2018.

account and include meteorological factors and data for pollen.

The observed acute effects of particulate matters on respiratory diseases could be explained by inducing an imbalance of systemic inflammation, oxidative stress, autophagy, and apoptosis, and by affecting epigenetic modification. Studies showed that elevated level of blood biomarkers of systemic inflammation (e.g., IL-6, IL-8 and TNF- α), coagulation (e.g., fibrinogen), soluble cluster of differentiation 40 ligands (sCD40L), soluble intercellular adhesion molecule-1 (sICAM-1), and fibrinogen, as well as DNA methylation levels were influenced by exposure to air pollutants (9–10).

This study was subject to some limitations. First, the acquisition of air pollution exposure data was from air monitoring stations, which might have some measurement errors. At the same time, the data of the monitoring station cannot fully represent the real exposure of patients, and there will be some exposure errors. Second, we did not obtain data on influenza, seasons and pollen, socioeconomic status, and daily activities, which may be some confounding factors related to outpatient visits and hospitalization. Third, we only analyzed the effects of one air pollutant on disease, but not the effects of exposure to multiple air pollutants. These deficiencies may make our results

FIGURE 2. Relative risk for chronic obstructive pulmonary disease (A) and asthma (B) outpatient visits per 10 $\mu\text{g}/\text{m}^3$ increase in concentrations of air pollutants with different lag days in 16 hospitals, 2013–2018.

deviate to a certain extent, which needs further exploration.

In conclusion, exposure to $\text{PM}_{2.5}$, O_3 , SO_2 , NO_2 , and CO has certain acute effects on outpatient and hospital admission of patients with COPD and asthma. Relevant susceptible people should try to reduce going out under the condition of air pollution to avoid aggravation of the disease. Meanwhile, these findings should be combined with disease diagnosis and treatment guidelines to guide clinical practice. This study not only paid attention to PM, but also emphasized that ozone cannot be ignored, which provides a reference for future research on the impact

of PM and ozone coordinated prevention and control and on the effects of carbon neutralization on health.
